# C++ Variables, Literals and Constants

In this tutorial, we will learn about variables, literals, and constants in C++ with the help of examples.

Content from <https://www.programiz.com/cpp-programming/variables-literals>.

## C++ Variables

In programming, a variable is a container (storage area) to hold data.

To indicate the storage area, each variable should be given a unique name (identifier). For example,

```
int age = 14;
```

Here, `age` is a variable of the `int` data type, and we have assigned an integer value 14 to it.

**Note:** The `int` data type suggests that the variable can only hold integers. Similarly, we can use the `double` data type if we have to store decimals and exponentials.

We will learn about all the data types in detail in the next tutorial.

The value of a variable can be changed, hence the name **variable**.

```
int age = 14;    // age is 14
age = 17;       // age is 17
```

---

## Rules for naming a variable

- A variable name can only have alphabets, numbers, and the underscore `_`.
- A variable name cannot begin with a number.

- It is a preferred practice to begin variable names with a lowercase character. For example, *name* is preferable to *Name*.
- A variable name cannot be a [keyword](#). For example, `int` is a keyword that is used to denote integers.
- A variable name can start with an underscore. However, it's not considered a good practice.

**Note:** We should try to give meaningful names to variables. For example, *first\_name* is a better variable name than *fn*.

---

# C++ Literals

Literals are data used for representing fixed values. They can be used directly in the code. For example: `1`, `2.5`, `'c'` etc.

Here, `1`, `2.5` and `'c'` are literals. Why? You cannot assign different values to these terms.

Here's a list of different literals in C++ programming.

---

## Integers

An integer is a numeric literal(associated with numbers) without any fractional or exponential part. There are three types of integer literals in C programming:

- decimal (base 10)
- octal (base 8)
- hexadecimal (base 16)

For example:

```
Decimal: 0, -9, 22 etc
Octal: 021, 077, 033 etc
Hexadecimal: 0x7f, 0x2a, 0x521 etc
```

In C++ programming, octal starts with a `0`, and hexadecimal starts with a `0x`.

---

# Floating-point Literals

A floating-point literal is a numeric literal that has either a fractional form or an exponent form. For example:

`-2.0`

`0.0000234`

`-0.22E-5`

**Note:** `E-5` =  $10^{-5}$

---

# Characters

A character literal is created by enclosing a single character inside single quotation marks. For example: `'a'`, `'m'`, `'F'`, `'2'`, `'{'` etc.

---

# Escape Sequences

Sometimes, it is necessary to use characters that cannot be typed or has special meaning in C++ programming. For example, newline (enter), tab, question mark, etc.

In order to use these characters, escape sequences are used.

| Escape Sequences | Characters |
|------------------|------------|
| <code>\b</code>  | Backspace  |
| <code>\f</code>  | Form feed  |
| <code>\n</code>  | Newline    |
| <code>\r</code>  | Return     |

|                 |                       |
|-----------------|-----------------------|
| <code>\t</code> | Horizontal tab        |
| <code>\v</code> | Vertical tab          |
| <code>\\</code> | Backslash             |
| <code>\'</code> | Single quotation mark |
| <code>\"</code> | Double quotation mark |
| <code>\?</code> | Question mark         |
| <code>\0</code> | Null Character        |

---

## String Literals

A string literal is a sequence of characters enclosed in double-quote marks. For example:

|                                 |   |
|---------------------------------|---|
| <code>"good"</code>             | string constant                           |
| <code>""</code>                 | null string constant                      |
| <code>" "</code>                | string constant of six white space        |
| <code>"x"</code>                | string constant having a single character |
| <code>"Earth is round\n"</code> | prints string with a newline              |

We will learn about strings in detail in the C++ string tutorial.

---

## C++ Constants

In C++, we can create variables whose value cannot be changed. For that, we use the `const` keyword. Here's an example:

```
const int LIGHT_SPEED = 299792458;
LIGHT_SPEED = 2500 // Error! LIGHT_SPEED is a constant.
```

Here, we have used the keyword `const` to declare a constant named `LIGHT_SPEED`. If we try to change the value of `LIGHT_SPEED`, we will get an error.

A constant can also be created using the `#define` preprocessor directive. We will learn about it in detail in the C++ Macros tutorial.

# C++ Data Types

In this tutorial, we will learn about basic data types such as int, float, char, etc. in C++ programming with the help of examples.

In C++, data types are declarations for variables. This determines the type and size of data associated with variables. For example,

```
int age = 13;
```

Here, *age* is a variable of type `int`. Meaning, the variable can only store integers of either 2 or 4 bytes.

---

## C++ Fundamental Data Types

The table below shows the fundamental data types, their meaning, and their sizes (in bytes):

| Data Type            | Meaning               | Size (in Bytes) |
|----------------------|-----------------------|-----------------|
| <code>int</code>     | Integer               | 2 or 4          |
| <code>float</code>   | Floating-point        | 4               |
| <code>double</code>  | Double Floating-point | 8               |
| <code>char</code>    | Character             | 1               |
| <code>wchar_t</code> | Wide Character        | 2               |
| <code>bool</code>    | Boolean               | 1               |
| <code>void</code>    | Empty                 | 0               |

Now, let us discuss these fundamental data types in more detail.

---

### 1. C++ int

- The `int` keyword is used to indicate integers.

- Its size is usually 4 bytes. Meaning, it can store values from - **2147483648 to 2147483647**.
- For example,

```
int salary = 85000;
```

## 2. C++ float and double

- `float` and `double` are used to store floating-point numbers (decimals and exponentials).
- The size of `float` is 4 bytes and the size of `double` is 8 bytes. Hence, `double` has two times the precision of `float`. To learn more, visit [C++ float and double](#).
- For example,

```
float area = 64.74;  
double volume = 134.64534;
```

As mentioned above, these two data types are also used for exponentials. For example,

```
double distance = 45E12    // 45E12 is equal to 45*10^12
```

## 3. C++ char

- Keyword `char` is used for characters.
- Its size is 1 byte.
- Characters in C++ are enclosed inside single quotes `' '`.
- For example,

```
char test = 'h';
```

**Note:** In C++, an integer value is stored in a `char` variable rather than the character itself. To learn more, visit [C++ characters](#).

## 4. C++ wchar\_t

- Wide character `wchar_t` is similar to the `char` data type, except its size is 2 bytes instead of 1.
- It is used to represent characters that require more memory to represent them than a single `char`.
- For example,

```
wchar_t test = L'א' // storing Hebrew character;
```

Notice the letter L before the quotation marks.

**Note:** There are also two other fixed-size character types `char16_t` and `char32_t` introduced in C++11.

---

## 5. C++ bool

- The `bool` data type has one of two possible values: `true` or `false`.
- Booleans are used in conditional statements and loops (which we will learn in later chapters).
- For example,

```
bool cond = false;
```

[https://www.youtube.com/embed/zB9RI8\\_wExo](https://www.youtube.com/embed/zB9RI8_wExo)

---

## 6. C++ void

- The `void` keyword indicates an absence of data. It means "nothing" or "no value".
- We will use void when we learn about functions and pointers.

**Note:** We cannot declare variables of the `void` type.

---

## Putting it all together

Run the following repl to see its results. Looking at the `main.cpp` file, a range of variables of different data types are declared at the top.

`cout` is used with the `+` operator to output the sum of two integers. `cout` is also used to display a message that includes the contents of the string variables, and lastly an if statement is used to present a message based on which letter is stored in the char variable.

Try doing each of the following, running the between each change:

1. Change the string variables to reflect your name
2. Change the values of the integers
3. Change the operator used in the output to `*`
4. Change the letter stored in the char variable to a grade you would like to receive
5. Change the integer variables to float, and assign decimal values.

---

## C++ Type Modifiers

We can further modify some of the fundamental data types by using type modifiers. There are 4 type modifiers in C++. They are:

1. `signed`
2. `unsigned`
3. `short`
4. `long`

We can modify the following data types with the above modifiers:

- `int`
- `double`

- char

# C++ Modified Data Types List

| Data Type          | Size (in Bytes) | Meaning   |
|--------------------|-----------------|---|
| signed int         | 4               | used for integers (equivalent to <code>int</code> )   |
| unsigned int       | 4               | can only store positive integers  |
| short              | 2               | used for small integers (range <b>-32768 to 32767</b> )   |
| unsigned short     | 2               | used for small positive integers (range <b>0 to 65,535</b> )                                    |
| long               | at least 4      | used for large integers (equivalent to <code>long int</code> )                                  |
| unsigned long      | 4               | used for large positive integers or 0 (equivalent to <code>unsigned long int</code> )           |
| long long          | 8               | used for very large integers (equivalent to <code>long long int</code> ).                       |
| unsigned long long | 8               | used for very large positive integers or 0 (equivalent to <code>unsigned long long int</code> ) |
| long double        | 12              | used for large floating-point numbers   |
| signed char        | 1               | used for characters (guaranteed range <b>-127 to 127</b> )                                      |
| unsigned char      | 1               | used for characters (range <b>0 to 255</b> )  |

Let's see a few examples.

```
long b = 4523232;
long int c = 2345342;
long double d = 233434.56343;
short d = 3434233; // Error! out of range
unsigned int a = -5;    // Error! can only store positive numbers or 0
```

## Derived Data Types

Data types that are derived from fundamental data types are derived types. For example: arrays, pointers, function types, structures, etc.

We will learn about these derived data types in later tutorials.
